Strandsone-karren på Voksa, Sande, Sunnmøre

Littoral karren at Voksa, Sande, Sunnmøre

At the island Voksa at Sunnmøre, a locality with littoral karren is found at a marble stripe just above the littoral zone. The Kamenitzas or bowl karren are circular to elliptical bowls, ca. 10 cm deep with detailed solution forms. Organic mud is probably an important source of acid, karstforming environment at this seawater influenced shoreline. Where wave action is more dominant, the bowls are eroded and the karst forms are missing.
